

HC(C) hd-TROSY-ECOSY processing Projection of the 3D matrix along F3

- Data are processed using standard FT procedure in F1 and F2 dimension. Linear prediction is used to double the number of time-domain points in the F3 dimension. Use macro “diag.com” to optimized this processing step before to start the projection. Signal in the (F2,F3) plan appears as an extensively folded diagonal. Use diag.tcl script to check if this 3D matrix is correctly processed : signal should appear on the red lines.
- Apply an F2-dependent frequency shift in the F3 dimension, such that the diagonal signals are now positioned vertically, using macro lines.com. Use lines.tcl script to check if this 3D matrix is correctly processed : signal should appear on the red lines.
- Vertical bands from the shifted spectrum are transposed and reassembled horizontally to construct an unfolded spectrum in the F2 dimension, using slide.com.
- Projection along F3 onto the F2 dimension: Use output 3D matrix from slide.com macro to optimized in F3 dimension the width of the central band containing the signal to extract. Extraction of signal, application of a sine-bell apodization window before projection along F3, is realized using xyz1.com macro. The resulting 2D matrix : test001.dat, is located in ft directory.
