Bethesda, Maryland, USA

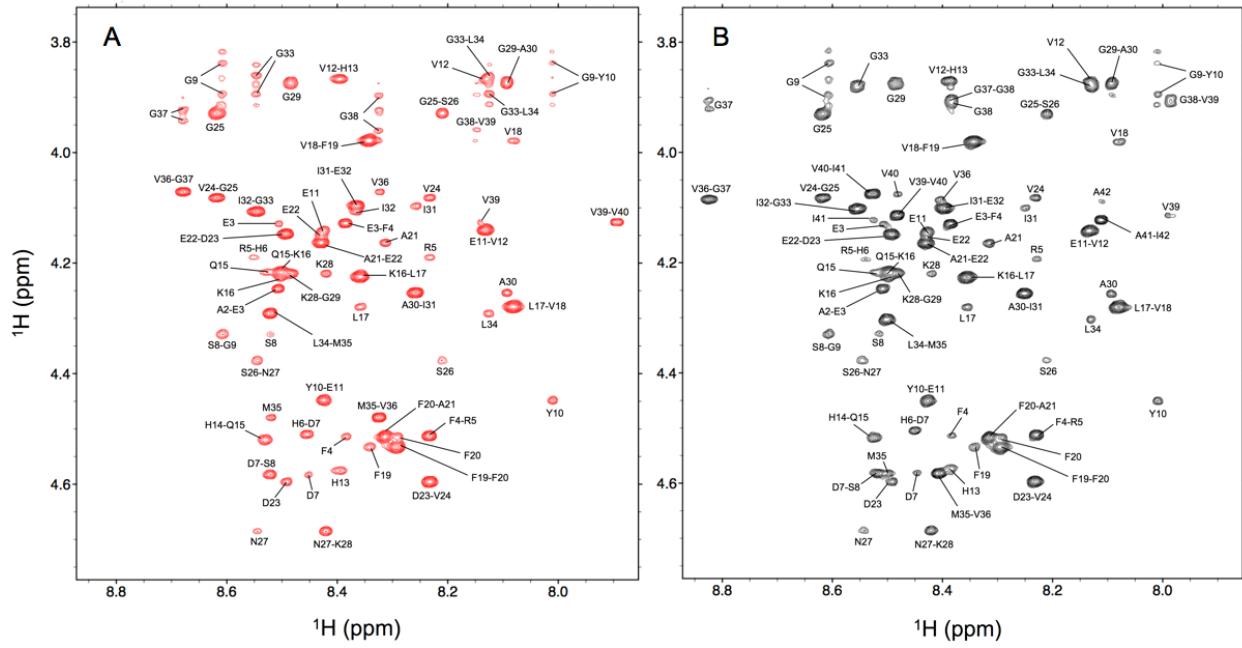

## **SUPPORTING INFORMATION**

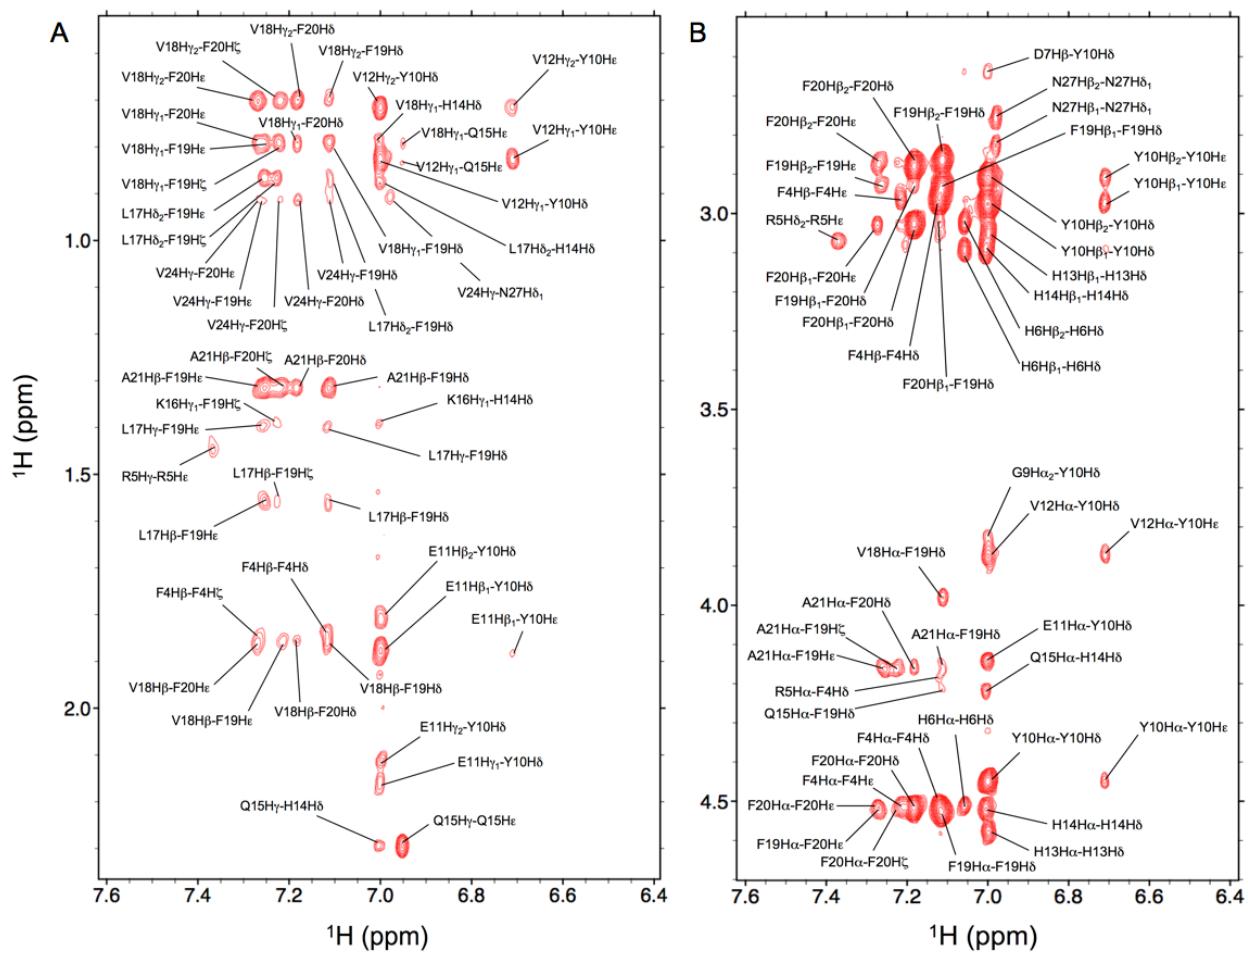

**Figure. S1 :** Comparison between the secondary  $^{13}\text{C}^\alpha$  measured in the present study and those reported by Yamaguchi et al.<sup>1</sup> for  $\text{A}\beta^{1-40}$  (A) and by Waelti et al.<sup>2</sup> for  $\text{A}\beta^{1-42}$  (B). The reference random coil values and corrections factors reported by Poulsen et coworkers<sup>3,4</sup> were used to calculate the secondary chemical shifts.

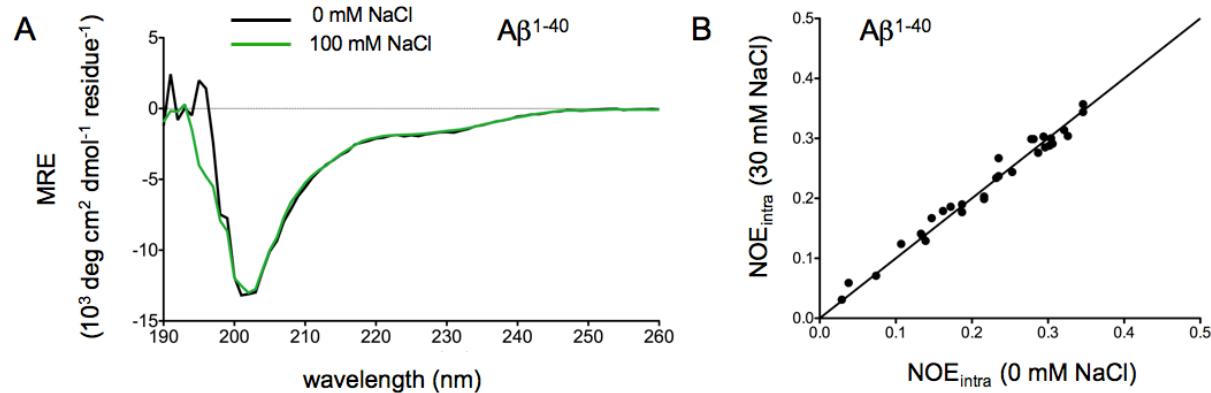

**Figure. S2 :** Comparison of the  $^3J_{\text{HNH}\alpha}$  coupling measured for  $\text{A}\beta^{1-40}$  and  $\text{A}\beta^{1-42}$  in (A) the present study and (B) reported in Sgourakis et al.<sup>5</sup> In each panel the residues presenting the largest  $^3J_{\text{HNH}\alpha}$  coupling differences between  $\text{A}\beta^{1-40}$  and  $\text{A}\beta^{1-42}$  are labeled.

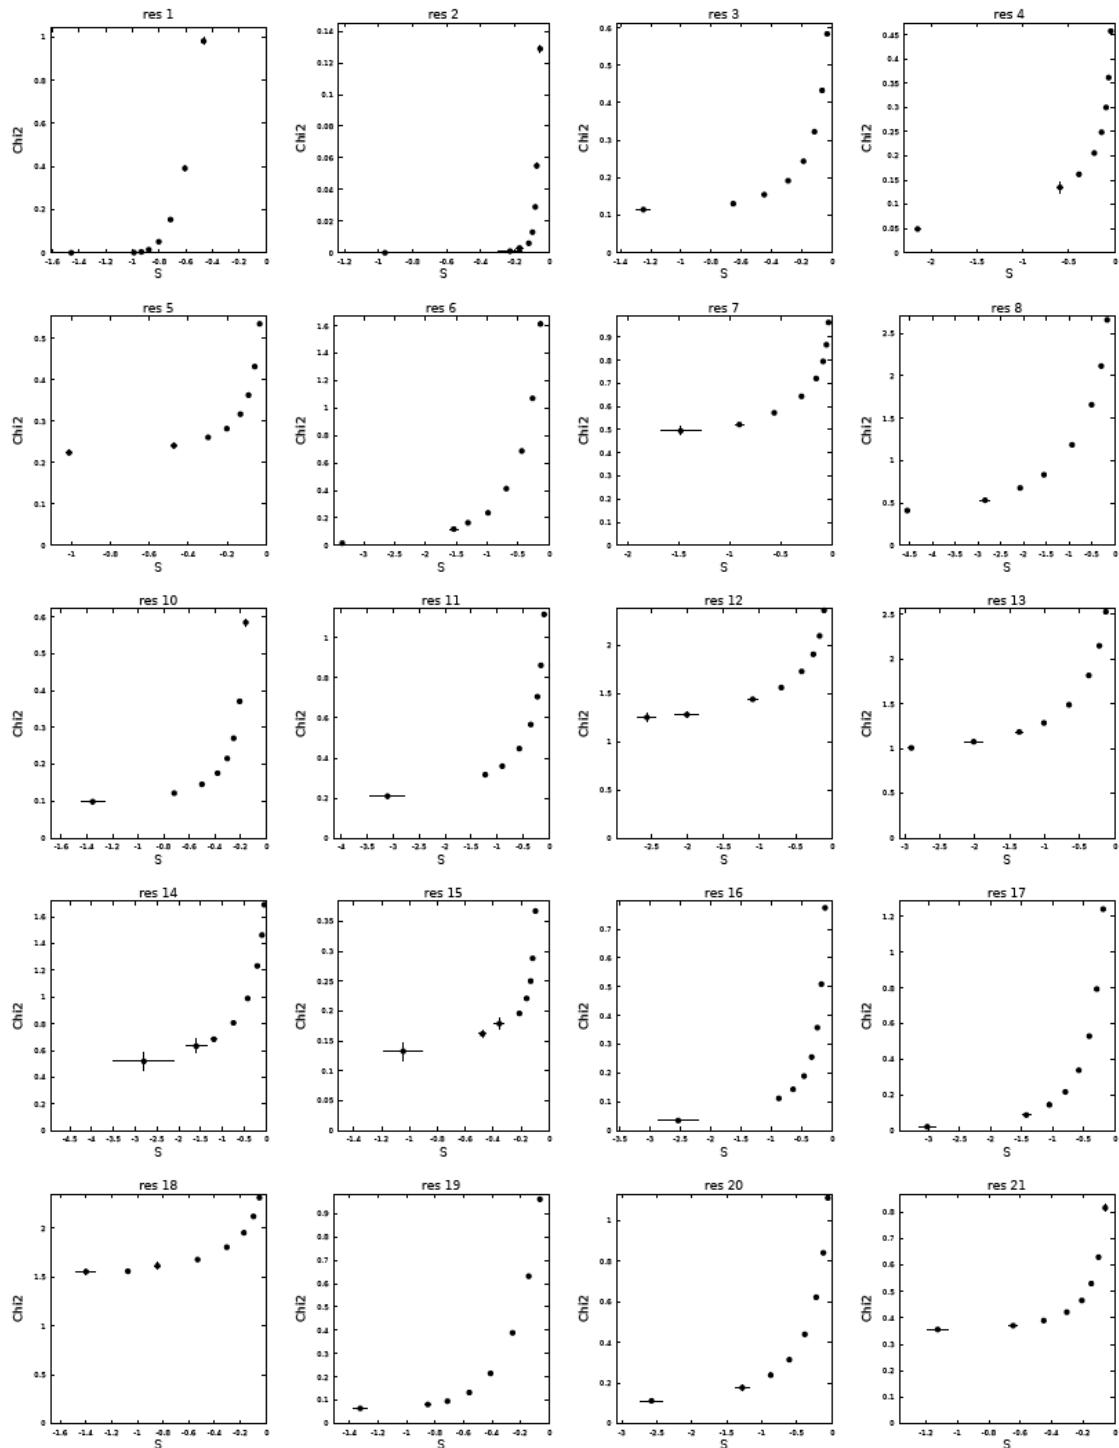

**Figure S3.** Expanded region of the 2D  $F_1$  BASH-decoupled NOESY spectrum recorded at 900 MHz for (A)  $\text{A}\beta^{1-40}$  and (B)  $\text{A}\beta^{1-42}$  at 277 K. The cross-peaks correspond to sequential and intraresidue couplings between the  ${}^1\text{H}^N$  and  ${}^1\text{H}^\alpha$  protons.

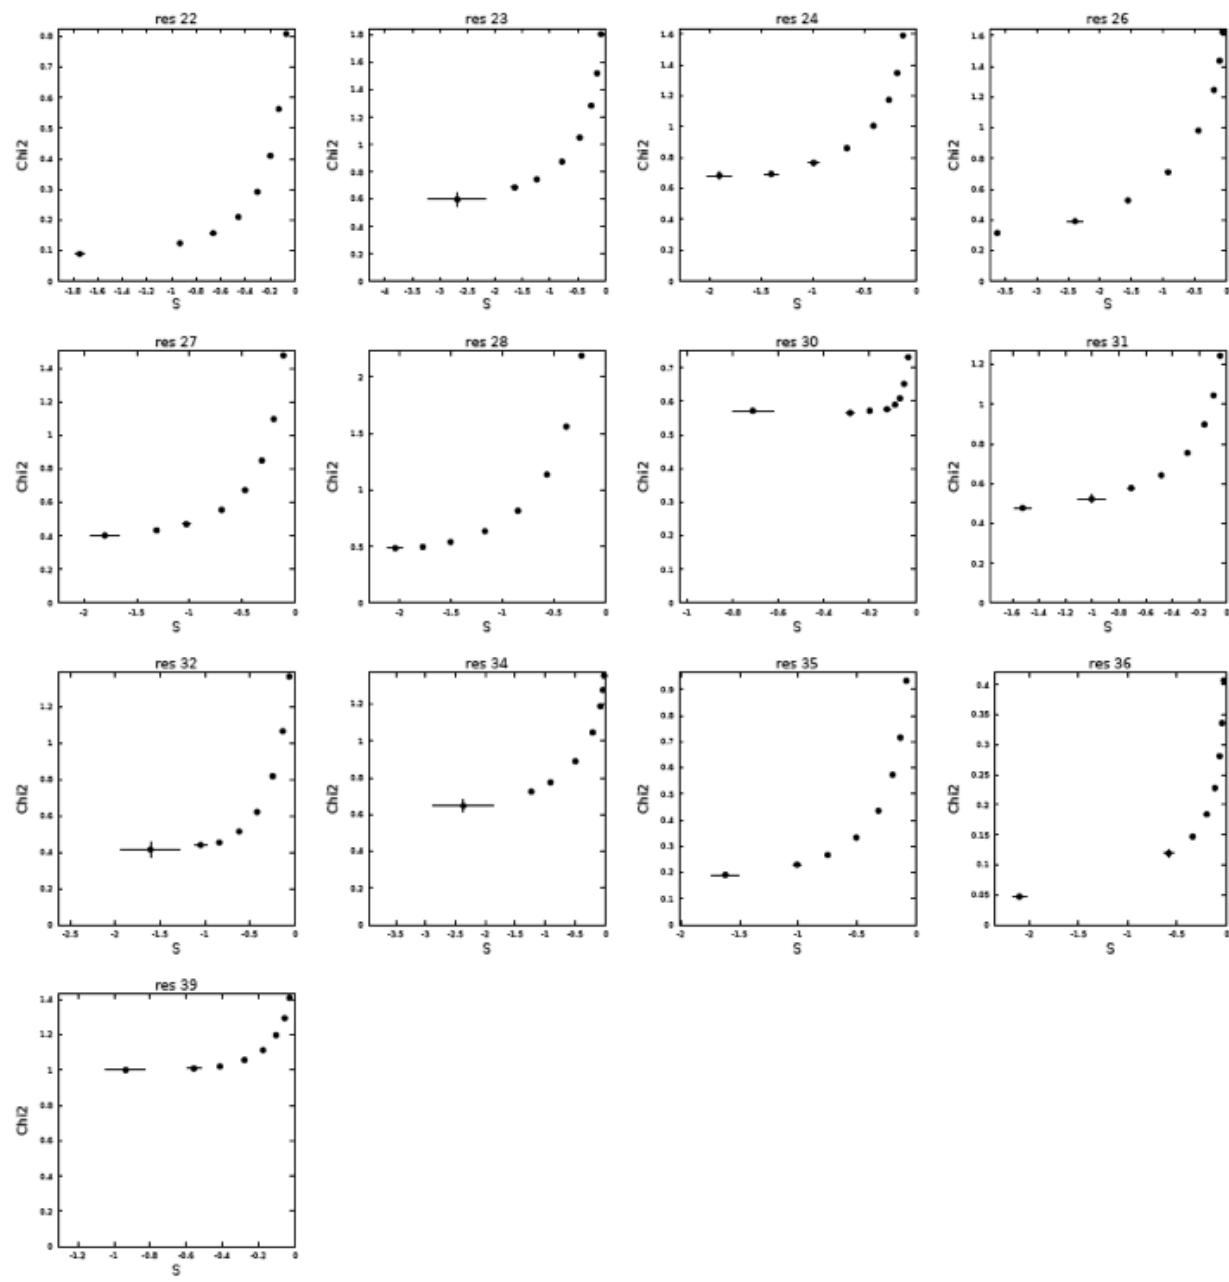

**Figure S4.** Expanded region of the 2D NOESY spectrum recorded at 900 MHz for the A $\beta$ <sup>1-40</sup> at 277 K. The aromatic region is shown with the corresponding assignment of the  $^1\text{H}$ - $^1\text{H}$  NOE contacts in (A) the aliphatic region and (B) the  $^1\text{H}^\alpha$  and  $^1\text{H}^\beta$  region.

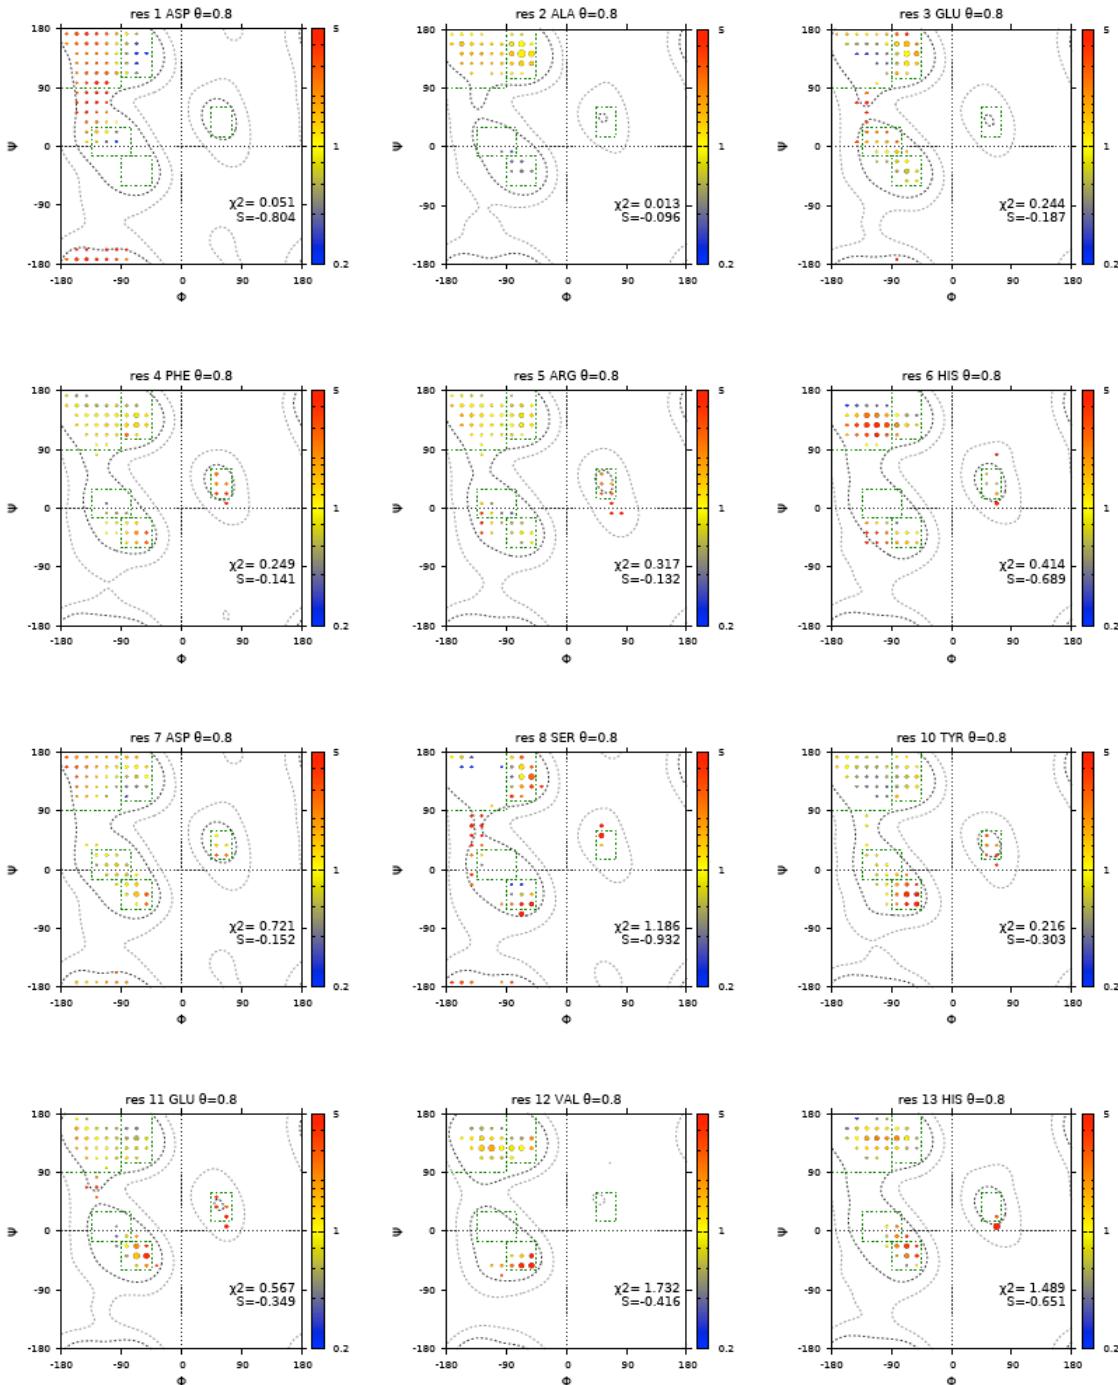

**Figure S5:** (A) Comparison of the CD spectra recorded at 288 K in 20 mM sodium phosphate pH 7.0, for 50  $\mu\text{M}$  samples of  $\text{A}\beta^{1-40}$  in the absence of NaCl (black) and in the presence of 100 mM NaCl (green). The CD spectra are recorded as the mean residue ellipticity (MRE). (B) Correlation between the intra-residue  $d_{\text{aN(i.i)}}$  NOE cross peak intensities extracted from 3D NOESY-HSQC spectra recorded at 277 K in 20 mM sodium phosphate pH 7.0 for 150  $\mu\text{M}$  samples of  $\text{A}\beta^{1-40}$  in the absence of NaCl and in the presence of 30 mM NaCl.

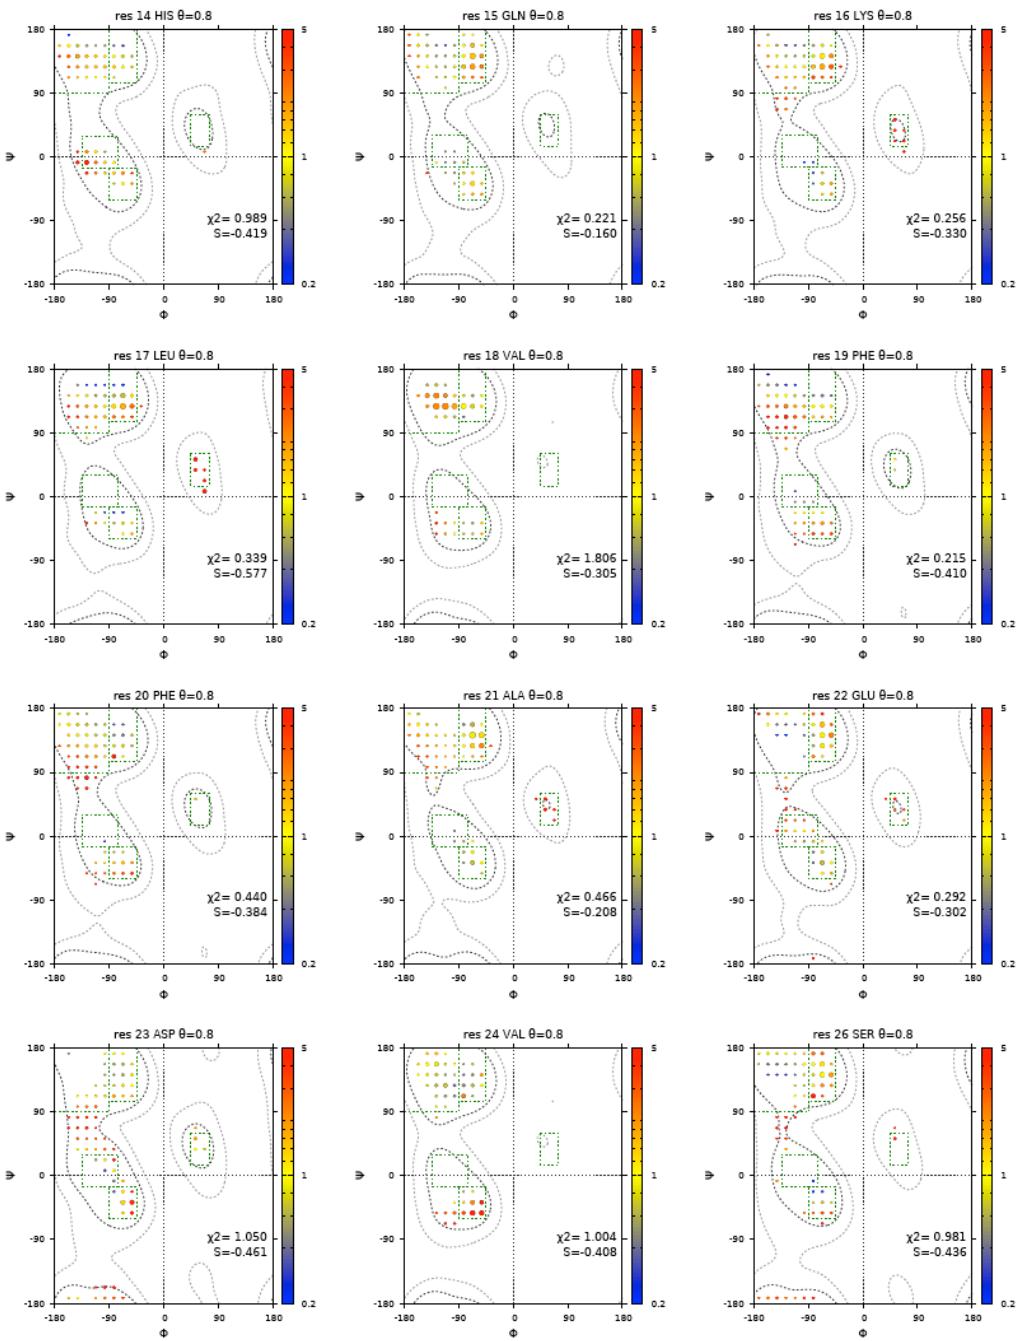

**Figure S6:** Plots of  $\chi^2$  versus  $S$ , the maximum entropy term, derived for different values of  $\theta$ , which controls the weight of the entropy term relative to that of the experimental data.<sup>6</sup> A set of  $\theta$ -values of (left to right) of 0, 0.1, 0.2, 0.4, 0.8, 1.6, 3.0, 6.0 and 10 was used here.

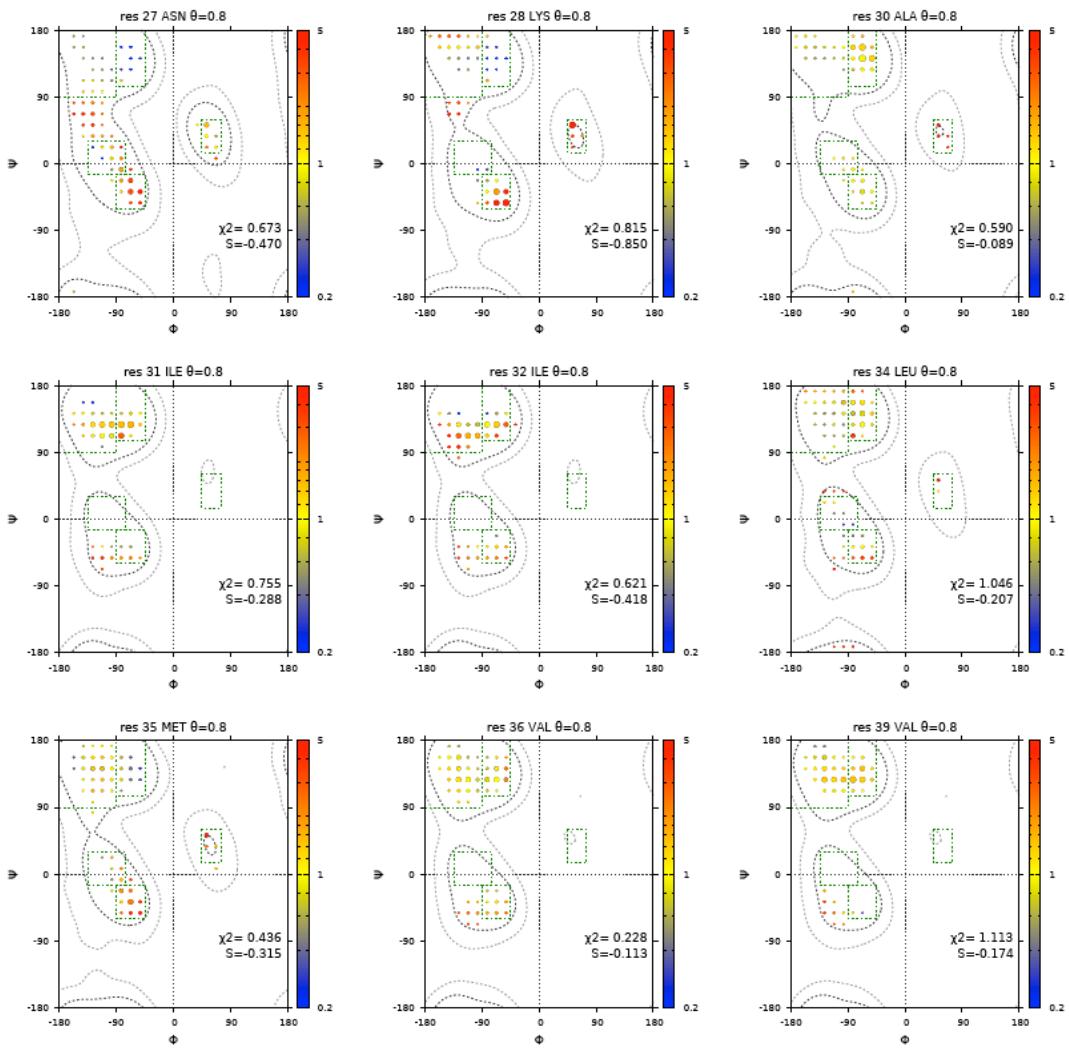

**Figure S6 (continued)**

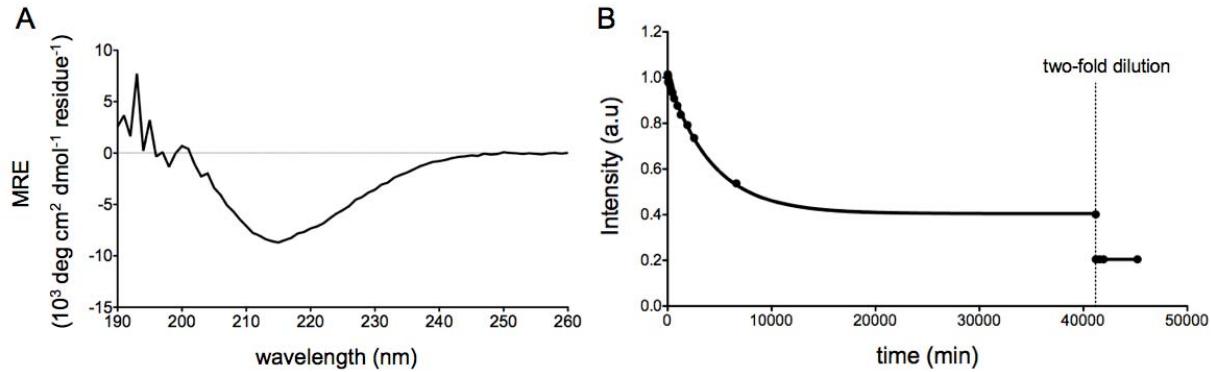

**Figure S7 (part1):**  $\phi/\psi$  torsion angle distributions derived for  $A\beta^{1-40}$  residues using the MERA webserver program.<sup>6</sup> The surface area of each circle is proportional to the population of its  $15^\circ \times 15^\circ$  voxel and the color of each circle reflects its fractional deviation from that seen in the coil database. Green boxes mark secondary structure regions:  $\beta$ , PPII,  $\alpha_L$ , type I  $\beta$ -turn ( $\beta$ -I) and  $\alpha_R$  (see Fig. 5, main text). An entropy weight factor of 0.8 and a diffusion anisotropy parameter  $k = 0.3$  were used. Heavy black dashed lines mark the edges of the most populated region of the residue-specific coil library and thin dashed lines mark the edges of sparsely populated regions.

**Figure S7 (continued).**

**Figure S7 (continued).**

**Figure S8:** (A) CD spectrum recorded at 288 K for a 150  $\mu\text{M}$  sample of  $\text{A}\beta^{1-42}$  in 20 mM sodium phosphate pH 7.0 ( $\text{H}_2\text{O}$  sample) after 28 days at 4°C (see Fig. 6 in the main text and panel B). (B) The same sample was also used to monitor the evolution of methyl group cross peak intensities of in a series of 2D  $^1\text{H}/^{13}\text{C}$  after a two-fold dilution (from 150  $\mu\text{M}$  to 75  $\mu\text{M}$ ). Inspection of the diluted sample after 1 month of further storage at 4°C showed vanishingly weak intensities, i.e., nearly full aggregation of the sample.
