**Materials and Methods**

**Preparation of NMR samples.**

Covalently linked di-ubiquitin (Ub₂) was constructed via an isopeptide bond linkage formed between the ε-amino group of a lysine side-chain of one monomeric unit (Ub₁), denoted as the ‘proximal’ domain in what follows, and the C-terminal carboxyl group of another monomeric unit, denoted as the ‘distal’ domain. Two types of linkages - through the side-chains of endogenous Lys⁶³ (K63) and Lys⁴⁸ (K48) of ubiquitin - were used in this study. The K63- and K48-linked Ub₂ were assembled enzymatically employing chain-terminating mutations as described in detail previously.⁵¹,² Specifically, the distal domain carried either K48R (in K48-Ub₂) or K63R (in K63-Ub₂) mutations, while the proximal domain had an additional Asp at the C-terminus. In each of the K63- and K48-linked Ub₂ only a single domain, either distal or proximal, was U-[¹⁵N²H]-labeled, with the other domain at natural isotopic abundance and hence ‘NMR-silent’ in heteronuclear NMR experiments, resulting in a total of four samples of Ub₂ for relaxation-based NMR studies in the absence and presence of lipid-based nanoparticles: (1) distal-U-[¹⁵N²H]-K63-Ub₂, (2) proximal-U-[¹⁵N²H]-K63-Ub₂, (3) distal-U-[¹⁵N²H]-K48-Ub₂, and (4)
proximal-U-[^{15}N\textsuperscript{2}H]-K48-Ub\textsubscript{2}. U-[^{15}N\textsuperscript{2}H]-labeled mono-ubiquitin (Ub\textsubscript{1}) was expressed and purified as described previously.\textsuperscript{51} All NMR samples were prepared in 10 mM phosphate buffer (K\textsubscript{2}HPO\textsubscript{4}/KH\textsubscript{2}PO\textsubscript{4}), pH 6.8, and 7\% D\textsubscript{2}O/93\% H\textsubscript{2}O. The final concentration of Ub\textsubscript{1} and Ub\textsubscript{2} following the addition of liposome solutions (see below) was 0.22 mM.

**Preparation and characterization of diamagnetic and paramagnetic liposomes.**

The sodium salt of 1-palmitoyl-2-oleoyl-sn-glycero-3-phospho-(1\'-rac-glycerol) (POPG), the gadolinium salt of 1,2-distearoyl-sn-glycero-3-phosphoethanolamine-N-diethylenetriaminepenta-acetic acid (18:0 PE-DTPA-Gd\textsuperscript{3+}) and cholesterol were purchased from Avanti Polar Lipids (Alabaster, AL).

Unilamellar vesicles were prepared by dissolving an aliquot of POPG and 20 \% (mol/mol) cholesterol in a chloroform:methanol (2:1) solution. For preparation of paramagnetic vesicles, 10\% (mol/mol) of 18:0 PE-DTPA-Gd\textsuperscript{3+} phospholipid was added to the lipid mixture. The solution was dried by slow evaporation of the organic solvent to a thin film on the walls of a round-bottom flask. Any trace of solvent was removed by keeping the lipid thin film under a stream of nitrogen for 3-4 hours. Re-hydration of the film was carried out by vortex agitation in 10 mM phosphate buffer (K\textsubscript{2}HPO\textsubscript{4}/KH\textsubscript{2}PO\textsubscript{4}), pH 6.8 to a final lipid stock concentration of 10 mM. For preparation of small unilamellar vesicles (SUV), rehydrated lipids were sonicated without cooling at 15 Watt for at least two 10-min cycles using a probe tip sonicator (Misonix, NY). Any titanium fragments released by the sonication tip were removed by centrifugation (8000 g x 10 minutes). Homogenous large unilamellar vesicles (LUV) were obtained by repeatedly extruding the lipid suspension through polycarbonate filters (successively 1 \textmu m, 400 nm and 100 nm pore sizes) to obtain uniformly sized unilamellar vesicles of \textasciitilde100 nm in diameter. Liposome solutions were stored in the dark above the transition temperature (T\textsubscript{m}) to prevent lipid oxidation. The size distribution of the vesicles was determined using dynamic light scattering (DLS) performed with a Zetasizer Nano ZS (Malvern Instruments, 4 mW He-Ne laser, \lambda\textsubscript{0} = 633 nm, \theta = 173\°). The measurements were repeated 5 times after a 2 min. temperature equilibration (25 \°C) on 1 mM (in lipid) samples.

**NMR relaxation measurements.**

All NMR experiments were recorded at 25 \°C using Bruker Avance-III spectrometers, equipped with Bruker TCI triple resonance z-axis gradient cryogenic probes operating at \textsuperscript{1}H Larmor frequencies of 700.24 and 500.68 MHz. All measurements in the presence of diamagnetic and paramagnetic POPG vesicles were carried out using protein:lipid ratios of 1:2 (mol/mol).
$^{15}$N-$R_2$ values in the absence and in presence of LUV and SUV liposomes were extracted from a combination of HSQC-based $^{15}$N $R_{1p}$ and $R_1$ measurements using procedures described previously. A $^{15}$N spin-lock field strength of 1.8 kHz was employed for the $^{15}$N $R_{1p}$ measurements to suppress any potential chemical exchange-induced line broadening. The following spin-lock periods were used in the $^{15}$N $R_{1p}$ experiments: 5, 10, 20, 40 and 60 ms at 700 MHz, and 5, 20, 40, 60 and 80 ms at 500 MHz. $^{15}$N-$R_1$ measurements were performed using delays of 40, 160, 240, 320 and 400 ms. Each 2D experiment comprised 128*×512* (500 MHz) or 128*×850* (700 MHz) complex points in the indirect ($^{15}$N) and direct ($^1$H) dimensions, respectively, corresponding to respective acquisition times of 100 ms and 73 ms at 500 MHz, and 72 ms and 87 ms at 700 MHz. Experiments were acquired with 16 scans per FID and an inter-scan delay of 2.0 s, resulting in net acquisition times of ~16 hr. per experiment.

$^1$H-$R_2$ relaxation experiments were carried out using standard procedures. Relaxation delays of 4, 8, 16, 24, 32 and 40 ms were used for the diamagnetic samples, while the delays of 2, 4, 8, 12, 16 and 20 ms were used for the paramagnetic samples.

NMR spectra were processed using the nmrPipe/nmrDraw suite of programs and the relaxation decays were best fit to a single exponential. Errors in the extracted rates were estimated from Monte Carlo simulations. Lifetime line-broadening ($\Delta R_2$) values were calculated as the difference between $^{15}$N or $^1$H N $R_2$ values obtained in the presence and absence of LUV/SUV vesicles. Amide proton ($^1$H$_\text{N}$) intermolecular transverse PRE rates ($\Gamma_{app}^2$) were obtained from the difference between the $R_2$ rates obtained in the presence of paramagnetic and diamagnetic LUVs.

### Calculation of $^{15}$N-$\Delta R_2$ in the presence of LUV and SUV liposomes.

In the absence of chemical shift differences between the free and bound states of the protein, the evolution of magnetization between the free (A) and bound (B) states is given by a simplified form of the Bloch-McConnell equations,

$$ \frac{d}{dt} \begin{bmatrix} I^A \\ I^B \end{bmatrix} = \begin{bmatrix} R_2^A + k_{\text{on}}^{\text{app}} & -k_{\text{off}} \\ -k_{\text{on}}^{\text{app}} & R_2^B + k_{\text{off}} \end{bmatrix} \begin{bmatrix} I^A \\ I^B \end{bmatrix} $$

(S1)

where $I^A$ and $I^B$ are the transverse magnetizations of states A and B, respectively; $k_{\text{off}}$ and $k_{\text{on}}^{\text{app}}$ are the dissociation and pseudo-first order apparent association rate constants; and $R_2^A$ and $R_2^B$ are the intrinsic transverse relaxation rates in the free and bound states, respectively (in the absence of exchange). $\Delta R_2$ values can be calculated by propagating Eq S1 and ‘reading off’ the transverse
magnetization of the (observable) state A at two separated time-points assuming single-exponential decay:

$$\Delta R_2 = \ln[I^A(\tau_1)/I^A(\tau_2)]/(\tau_2 - \tau_1)$$  \hspace{1cm} (S2.1)

where the delays $\tau_1$ and $\tau_2$ were set to 10 and 70 ms (for $^{15}$N-$\Delta R_2$ LUV) and 10 and 30 ms (for $^{15}$N-$\Delta R_2$ SUV). $\tau_1$ was chosen to remove any small deviations from single-exponential behaviour and $\tau_2$ was chosen to match the order of magnitude of the experimental decay.

Approximate solutions of Eq S1 can be obtained by retaining only the leading term in the characteristic polynomial of the evolution matrix on the right-hand side of Eq S1.\textsuperscript{58} Using this approach, it can be shown that $\Delta R_2$ is to a very good approximation given by,

$$\Delta R_2 = k_{\text{on}}^{\text{av}} \frac{\Delta R}{k_{\text{eff}} + \Delta R} = k_{\text{on}}^{\text{av}} \frac{R_2^B}{k_{\text{eff}} + R_2^B}$$  \hspace{1cm} (S2.2)

where $\Delta R = R_2^B - R_2^A$ is for both LUV and SUV interactions $R_2^B >> R_2^A$. Note that in the limit of fast exchange ($k_{\text{off}} >> k_{\text{on}}^{\text{av}}$) and for highly skewed populations ($k_{\text{off}} >> k_{\text{on}}^{\text{av}}$), $\Delta R_2 = p_B R_2^B$, where $p_B$ is the population of the bound state B.

**Calculation of $^{15}$N transverse spin relaxation rates in the bound state**

In an isolated $^{15}$N-H spin-pair, the $^{15}$N-$R_2$ is accounted for by the sum of two mechanisms, $^{15}$N-$^1$H dipolar interaction and $^{15}$N chemical shift anisotropy (CSA), and is related to molecular motions of Ub$_2$ on the surface of liposomes through their dependence on linear combinations of the spectral density function $J$ evaluated at a finite number of frequencies $\omega$:\textsuperscript{59}

$$^{15}$N-$R_2 = 0.05(\gamma_H^2\gamma_N^2\hbar < r_0^{3/2}>)^2[4J(0) + J(\omega_H - \omega_N) + 3J(\omega_N) + 6J(\omega_H + \omega_N)]$$

$$+ (1/45)\omega_N^2(\sigma_1^z - \sigma_1^z)^2(3J(\omega_N) + 4J(0))$$  \hspace{1cm} (S3)

where $\gamma_H$ and $\gamma_N$ are the gyromagnetic ratios of $^1$H and $^{15}$N nuclei, respectively; $\hbar$ is Planck’s constant divided by $2\pi$; $r_{0\text{NN}}$ is the N-H bond length (1.02 Å); and $(\sigma_1^z - \sigma_1^z)$ is the $^{15}$N CSA (-170 ppm), where $\sigma_1$ and $\sigma_z$ are the parallel and perpendicular components of the axially symmetric $^{15}$N chemical shift tensor. The form of the spectral density function $J$ adopted in this work is specified in Eq. 2 of the main text.
Construction of the target error function.

The minimization of the following error function $F$ was performed in the combined analysis of LUV and SUV $^{15}$N-$\Delta R_2$ data for each distal/proximal K63/K48-linked sample of Ub$_2$,

$$F = \alpha_1 \left( \frac{\Delta R_{2,LUV}^{\text{obs}} - \Delta R_{2,LUV}^{\text{calc}}}{\sigma_{\Delta R_{2,LUV}}} \right)^2 + \alpha_2 \left( \frac{\Delta R_{2,SUV}^{\text{obs}} - \Delta R_{2,SUV}^{\text{calc}}}{\sigma_{\Delta R_{2,SUV}}} \right)^2$$

(S4)

where the subscript $i$ refers to residue number, $\sigma$ represents the standard error of the measurement, and $\alpha_1, \alpha_2$ are the scaling factors that define the relative contribution of LUV and SUV data to the total error function. Throughout this work, we report the values obtained with $\alpha_1 = \alpha_2 = 1$ ensuring the same weight for LUV and SUV data.

$\Delta R_{2}^{\text{calc}}$ in Eq. S4 is equal to $\Delta R_{2}^{\text{overall}}$ of the main text and consists of two contributions,

$$\Delta R_{2}^{\text{calc}} = \Delta R_{2}^{\text{overall}} = \Delta R_{2} + F_{\text{iso}}$$

(S5)

where $\Delta R_2$ is calculated using Eq. S2.1 after propagation of Eq. S1 or Eq. S2.2, the relaxation rates $R_2^B$ are calculated using Eq. S3 combined with Eq. 2 of the main text, and $F_{\text{iso}}$ represents a uniform contribution to $^{15}$N-$\Delta R_2$ that takes into account the two additional binding modes of a given Ub$_2$ domain, i.e. modes (2) and (3) in Fig. 1D of the main text. Using Eqs. S5 and S2.2 and considering that in the macromolecular limit, only the spectral density at zero frequency contributes significantly to the relaxation rates, $F_{\text{iso}}$ for SUV interactions, $F_{\text{iso}}^{\text{SUV}}$, can be recast, for example, in the following form,

$$F_{\text{iso}}^{\text{SUV}} = \Delta R_{2}^{\text{max}}_{\text{SUV}} - k_{\text{on}}^{\text{app,SUV}} K_R (\tau_{C}^{\text{SUV}} + \tau_{w}^{\text{SUV}}) / k_{\text{eff}}$$

(S6)

where $\Delta R_{2}^{\text{max}}_{\text{SUV}}$ is chosen for simplicity because $[P_2(\cos\alpha)]^2 = 1$ in this case, $K_R$ is a constant that incorporates dipolar and CSA relaxation constants in Eq. S3 and $S_{w}^2 = 0.5$ ($K_R \sim 0.775 \times 10^9$ s$^{-1}$), and the rest of the parameters are defined in the main text. A similar expression can be obtained for $F_{\text{iso}}^{\text{LUV}}$. Eq. S6 shows that $F_{\text{iso}}$ is linearly anti-correlated with the apparent association rate constant $k_{\text{on}}^{\text{app}}$. Simultaneous determination of $F_{\text{iso}}$ and $k_{\text{on}}^{\text{app}}$ by non-linear least squares fitting procedures is therefore very problematic without additional assumptions about either of the two parameters.
The set of global variable parameters of the fit thus comprises: \( \{k_{\text{on}}^{S\text{UV}}; k_{\text{off}}; \tau, \theta; \varphi; F_{\text{iso}}^{S\text{UV}}\} \) when a single \( F_{\text{iso}}^{S\text{UV}} \) was used (i.e. when \( F_{\text{LUV}}^{\text{iso}} \) was assumed to be equal to \( F_{\text{SUV}}^{\text{iso}} \)), and \( \{k_{\text{off}}; \tau, \theta; \varphi; F_{\text{LUV}}^{\text{iso}}; F_{\text{SUV}}^{\text{iso}}\} \) when this assumption was dropped, and the value of \( k_{\text{on}}^{S\text{UV}} \) was fixed at the value obtained with \( F_{\text{LUV}}^{\text{iso}} = F_{\text{SUV}}^{\text{iso}} \), minus four times the uncertainty in the fit (see main text). The minimizations of the target function in Eq. S4 were performed using home-written Matlab software (MathWorks Inc. MA). The uncertainties in the values of the optimized parameters, corresponding to confidence intervals of \( \pm 1 \) S.D., were determined from the variance-covariance matrix of the non-linear fit. Convergence of the solution was confirmed by varying initial values for all parameters and obtaining the same solution within the reported errors.

**Relationship to spectral density function of Brainard & Szabo**

In the notation adopted in this work (see Eq 2 of the main text), the correlation function, \( C(t) \), derived by Brainard and Szabo to describe internal rotation of a bond vector around a symmetry axis defined in the molecular frame when the axis undergoes diffusive motions (wobbling) around its equilibrium position, has the following form,

\[
C(t) = \exp(-t/\tau_C) \sum_{b=-2}^{2} \exp(-b^2t/6\tau) \left[ d_{b0}^{(2)}(\alpha) \right]^2 \left[ S_w^2 + (1-S_w^2)\exp\left[-(t-b^2t/6)/\tau_w\right]\right]
\]  

(S7)

where \( d_{b0}^{(2)}(\alpha) \) are reduced elements of the Wigner rotation matrix of order 2:

\[
d_{00}^{(2)}(\alpha) = (3\cos^2(\alpha) - 1)/2; \quad d_{\pm 10}^{(2)}(\alpha) = \sqrt{3/2}\sin(\alpha)\cos(\alpha); \quad d_{\pm 20}^{(2)}(\alpha) = \sqrt{3/8}\sin^2(\alpha)
\]

(S8)

After Fourier transformation of Eq. S7, we obtain,

\[
J(\omega) = S_w^2[P_1(\cos \alpha)]^2 \frac{\tau_C}{1 + (\omega \tau_C)^2} + S_w^2\left[3\cos^2 \alpha \sin^2 \alpha\right] \frac{\tau_{t'}^4}{1 + (\omega \tau_{t'})^2} + \frac{(3/4) \sin^4 \alpha}{1 + (\omega \tau_{t''})^2}
\]

\[
+ (1 - S_w^2)\left[P_2(\cos \alpha)]^2 \frac{\tau_w^4}{1 + (\omega \tau_w^2)} + [3\cos^2 \alpha \sin^2 \alpha\right] \frac{\tau_{w'}^4}{1 + (\omega \tau_{w'})^2} \left[(3/4) \sin^4 \alpha\right] \frac{\tau_{w''}^4}{1 + (\omega \tau_{w''})^2}
\]

(S9)

where

\[
\tau_{t'} = (1/\tau_C + 1/6\tau_t)^{-1}; \quad \tau_{t''} = (1/\tau_C + 2/3\tau_t)^{-1}; \quad \tau_{w'} = (1/\tau_C + 1/\tau_w)^{-1};
\]

\[
\tau_{w''} = (1/\tau_C + 1/6\tau_t + 1/\tau_w - 1/6\tau_w)^{-1}; \quad \tau_{w''} = (1/\tau_C + 4/6\tau_t + 1/\tau_w - 4/6\tau_w)^{-1}.
\]
Note that the rotational and wobbling motions in Eq. S9 are inter-dependent, and *a-priori* no assumptions are necessary as to their relative time-scales ($\tau_\text{r}$ and $\tau_w$). Eq S9 is to be compared with Eq 2 of the main text. As $\sum_{b=-2}^{2} \left[ d_{b0}^{(2)}(\alpha) \right]^{2} = 1$, if $\tau_r''$ is assumed to be equal to $\tau_r'$, then the second term in Eq S9 can be reduced to $S_{\text{c}}^2 \left( 1 - [P_2(\cos \alpha)] \right)^{2} \frac{\tau_r'}{1 + (\omega \tau_r')^{2}}$ which is equivalent to the second term in Eq 2 of the main text. The use of the spectral density function in Eq. S9 instead of that in Eq. 2 of the main text yields the parameters of exchange and dynamics of ubiquitin-liposome interactions that are very similar to those reported in the main text, except that the derived values of $\tau_\text{r}$ are approximately equal to 1/6 of the reported values by virtue of the different definitions of the effective correlation times of rotational motion in Eq S8 and Eq 2 of the main text.

Figure S1. $^{15}$N-$\Delta R_2$ profiles obtained for the distal (shown in red) and proximal (in blue) domains of (A) K63-linked and (B) K48-linked di-ubiquitin (Ub$_2$) in the presence of negatively charged POPG LUVs (solid lines) and SUVs (dashed lines). The [$^{15}$N/$^2$H]-labeled domain in the various Ub$_2$ constructs is depicted by a filled-in circle in the cartoon representations shown in each panel. All the experimental data were collected at pH 6.8, 25 °C using 1:2 protein:lipid molar ratios at a protein concentration of 0.22 mM. The larger average value of $\Delta R_2$ observed in the presence of SUVs compared to LUVs is the result of two competing factors: the population of the bound state, $p_B$ and the total effective correlation time $\tau_C$. Assuming the same $k_{off}$ for LUVs and SUVs, the larger value of $p_B$ for SUVs than LUVs is due to a larger value of $k_{on}^{app} \cdot k_{off}^{app}$ is the product of the second order association rate constant $k_{on}$. For a purely diffusion controlled reaction, the former is proportional to the radius of the nanoparticles, while the latter is inversely proportional to the cube of the radius of the nanoparticles. Thus, $k_{on}^{app}$ is approximately proportional to the inverse square of the nanoparticle radius, which in this instance is $\sim$16 times larger for SUVs than LUVs (see main text Table 1). $\tau_C$, on the other hand, is dependent on both the rotational correlation time of the nanoparticle and the exchange rate ($k_{ex} \sim k_{off}$). From Table 1 of the main text the ratio of $\tau_C$ for LUVs to SUVs ranges from $\sim$9 to $\sim$13.
Figure S2. (A) $^{15}\text{N}-\Delta R_2$ profiles obtained for mono-ubiquitin ($\text{Ub}_1$) in the presence of POPG LUVs (filled symbols) and SUVs (open symbols). (B) Amide proton ($^1\text{H}_\text{N}$) intermolecular transverse PREs ($\Gamma_2$) observed for $\text{Ub}_1$ in the presence of negatively charged Gd$^{3+}$-tagged POPG LUVs. All the experimental data were collected at pH 6.8, 25 °C, and a 1:2 protein:lipid molar ratio with a protein concentration of 0.22 mM.
Figure S3. Dependence of $^{15}\text{N}-\Delta R_2$ on (A) nanoparticle size (SUV vs. LUV), and (B) magnetic field strength (700 and 500 MHz) measured on the $[^{15}\text{N}/^2\text{H}]$-labeled distal domain of K63-linked Ub$_2$ (represented by the filled-in circle in the cartoon representations shown in each panel). The average ratio of $^{15}\text{N}-\Delta R_2$ values at 700 to 500 MHz is 1.19, in good agreement with the calculated ratio of 1.20 from a relaxation mechanism based on the one-bond $^1\text{H}^{15}\text{N}$ dipolar interaction and a -170 ppm $^{15}\text{N}$ chemical shift anisotropy. All the experimental data were collected at pH 6.8, 25 °C, and a 1:2 Ub$_2$:lipid molar ratio with a protein concentration of 0.22 mM.
Figure S4. Mapping of $^1$H$_N$ intermolecular PREs on surface representations of K48- and K63-linked di-ubiquitin (Ub$_2$). Crystal structures of K48-linked Ub$_2$ in (A) the closed state (PDB ID 1AAR) and (B) the open state (PDB 3NS8). (C) Crystal structure of K63-linked Ub$_2$ (PDB ID 3H7P). PREs are color-coded from red (~18-20 s$^{-1}$) to white for the distal domains and from blue (~16-18 s$^{-1}$) to white for the proximal domains (the background is ~6.5 s$^{-1}$ in both cases). Residues Leu$^8$, Ile$^{44}$, Val$^{70}$ that form a surface hydrophobic patch in each Ub unit are shown in green.
Figure S5. Calculated theoretical dependence of the ratio $R = (\Delta R_2^{\text{max}} - F_{\text{SUV}}^{\text{iso}}) / (\Delta R_2^{\text{min}} - F_{\text{SUV}}^{\text{iso}})$ on the correlation time of internal rotation $\tau_r$ for di-ubiquitin (Ub$_2$) on the surface of SUV nanoparticles. The ratios $R$ are calculated with the exchange and dynamics parameters of interactions with SUV liposomes for K63- and K48-linked Ub$_2$ constructs (left and right panels, respectively) using the upper bounds for $F_{\text{SUV}}^{\text{iso}}$ reported in Table 1 of the main text. Experimental ratios $R$ obtained in the presence of SUVs and the corresponding $\tau_r$ values (approximately equal to the lower bounds reported in Table 1 of the main text) are indicated for distal (red dashed lines) and proximal (blue dashed line) domains of the K63- and K48-linked Ub$_2$. The [${}^{15}$N/²H]-labeled domain is depicted by a filled-in circle (red, distal; blue, proximal) in the cartoon representation in each panel.
